Abstract

We analyze the quantization of dynamical systems that do not involve any background notion of space and time. We give a set of conditions for the introduction of an intrinsic time in quantum mechanics. We show that these conditions are a generalization of the usual procedure of deparametrization of relational theories with hamiltonian constraint that allow to include systems with an evolving Hilbert Space. We apply our quantization procedure to the parametrized free particle and to some explicit examples of dynamical system with an evolving Hilbert space. Finally, we conclude with some considerations concerning the quantum gravity case.

1 Introduction

The concept of time enters in the basic formalism of quantum mechanics in two ways: to mark the evolution of the system and to order a sequence of measurements. In terms of Von Neumann [1] axiomatic formulation time enters as evolution labeling parameter in axiom IV through the evolution equation (Schroedinger equation) and implicitly in axiom II through the possible dependence of the operators corresponding to observables on time. On the other hand time appears as sequence ordering label in axiom V, through the fact that the outcome of a measurement depends on previous measurements. Furthermore this time parameter is assumed to be given in advance. The picture that we get is a unit vector in a Hilbert space (which depends on the system and is given once and forever, following axiom I) with a smooth time evolution generated by the hamiltonian operator via the Schroedinger equation with discontinuous leaps

corresponding to measurements.

The Dirac [2] quantization procedure for constrained systems doesn't introduce major changes in this picture, considering that it assumes the existence of a non vanishing hamiltonian in addition to the set of constraints, and a standard Schroedinger equation with that hamiltonian. There exist however a wide class of models for which, at the end of the application of the usual thumb rules of quantization, one is left only with a set of constraint equations (in addition, of course, of the commutation algebra of the fundamental dynamical variables), without neither a non zero hamiltonian nor a natural choice of a time parameter. This situation is characteristic for instance of reparametrization invariant systems (see [3]), sometimes called generally covariant systems. The example of greatest physical interest of this kind of theories is undoubtedly General Relativity, where the problem is known as "the issue of time" [4, 5].

Our aim in this paper is twofold. Firstly we intend to propose the necessary changes in the standard formalism of quantum mechanics in order to deal with the above mentioned kind of systems, which we will call "totally constrained systems". This involve to put forward a prescription to slice the representation space in which we will realize the commutation algebra of the dynamical variables in equal "time" spaces as well as define this "time". Then we will explore the logical possibility of the slices being non isomorphic. This could be considered, from the point of view of standard quantum mechanics, as a change in time or evolution of the Hilbert space describing the system.

The motivation to consider the possibility of "evolving Hilbert spaces" comes from the conceptual point of view from the suggestion, due to Unruh [9], that quantum gravity should have this property. The main point of his argument is the following: Does the Big Bang theory for the origin of the Universe means that because there was less space early and there were also fewer physical attributes that the Universe had? His answer is yes and it is based in the fact that there should be some limit at the Planck length to the number of different values that any field could take. If this observation is true one should describe the universe with a finite dimensional Hilbert space and a set of operators which both change in time¹. This proposal seem to be very appealing both from a physical and philosophical point of view. In fact in a description of the universe in terms of fixed Hilbert space, the set of possible behaviors of the universe is fixed at all times from the very beginning. That means that the state that describes the present behavior of the universe with its enormous complexity was a vector of the Hilbert space since the Big Bang. In practice the observed evolution from the simple to the complex is nothing but the evolution between different possible behaviors. In quantum mechanics a system is identified with

¹A similar proposal was made by Jacobson [10]

its Hilbert space, the set of all its possible behaviors (states). Hence, in this picture, the universe is given once and for all.

Furthermore, if the Hilbert space is fixed, the initial conditions of the universe are not determined by its dynamical laws and the actual initial conditions remains completely unexplained. Hartle [11] has stressed the reasons for the search of a theory for the initial conditions of the universe. Initial conditions are crucial to explain the large scale homogeneity and isotropy of the universe, its approximate spatial flatness, the spectrum of density fluctuations, the homogeneity of the arrow of time and the existence of a classical space time.

Of course, the usual quantum mechanical systems like particles are described by a fixed set of attributes as position and momentum and a fixed Hilbert space, but for these systems we have no reason to expect different behaviors for different times, and in principle any conceivable initial state may be prepared by measuring a suitable CSCO.

In this work, as we said before, we are interested in the identification of an intrinsic time in totally constrained dynamical systems. We shall give a set of conditions for the definition of a physical time that generalize the usual deparametrization procedure. We shall see that the introduction of a physical time in these systems naturally leads to the possibility of evolving Hilbert spaces.

Some systems that usually require the introduction of a nonpositive definite inner product or a decomposition between positive and negative frequency states may now be quantized in terms of a positive definite inner product with an evolving Hilbert space. In general, evolving Hilbert spaces seem to be naturally related with systems with boundaries or involving operators that satisfy a non canonical algebra.

As it was noticed by Unruh, evolving Hilbert spaces are naturally related with systems with a finite number of degrees of freedom. In fact, in the infinite dimensional case, it is always possible to describe the system in terms of a fixed Hilbert space, but we shall prove that, in this case, relational systems may behave as the continuum limit of systems with a finite dimensional evolving vector space. In particular, the transition amplitudes will remain invariant while the system evolves into the future, but the system will not be invariant under time reversal, and the evolution will not be unitary. We shall call this kind of infinite dimensional systems evolving systems.

In section 2 we introduce a description of the quantum mechanics of totally constrained dynamical systems and show that this description naturally generalizes the quantization procedure of deparametrizable systems. In section 3 we are going to apply this description to three examples. The parameterized classical free particle, a finite dimensional constrained system with an evolving vector space of states and an infinite dimensional evolving system associated with the Klein Gordon model.

Finally, in section 4, we shall conclude with some final remarks concerning the application of this procedure to the quantum gravity case.

2 Time and quantization of totally constrained dynamical systems

We will assume that we have, in general as the outcome of a standard hamiltonian formulation of the theory under study, a set of constraint equations

$$\phi_i(q_a) = 0 \text{ with } i = 1, \dots, n+1 \quad (1)$$

written in terms of the dynamical variables q_a , with $a = 1, \dots, f$ of the theory as well as the commutation (or anticommutation) algebra of these variables

$$[q_a, q_b]_{\pm} = \alpha_{ab}^c q_c + \beta_{ab} \quad (2)$$

Notice that if

$$\alpha_{ab}^c = 0 \quad (3)$$

$$\beta_{ab} = i \quad (4)$$

then q_a and q_b are canonically conjugated variables. From the algebra of the q 's it follows the algebra of the constraints

$$[\phi_i, \phi_j]_{\pm} = f_{ij}^k(q_a) \phi_k \quad (5)$$

which we assume closed (or the constraints to be first class), but allowing the "structure constants" to depend on the q 's. We will assume furthermore that one of the constraints is singled out (as it is the case in concrete examples) from a physical point of view or considerations from the classical theory as containing implicitly the information about the time evolution of the system, and we will call it *hamiltonian constraint* $\mathcal{H}$. We will call the remaining n constraints *kinematical constraints* $\mathcal{D}_i$.

In order to have a sensible quantum theory out of the previous information we need to fulfill several steps.

The first ones, more or less straightforward, are:

(1) To find a vector space $\mathcal{E}_R$, which we will call *representation space*, in which realize the algebra of the q 's

(2) To construct the subspace $\mathcal{E}_K$, which we will call *kinematical space* given by the solutions $|\psi_K\rangle$ of the whole set of kinematical constraints

$$\mathcal{D}_i |\psi_K\rangle = 0 \quad (6)$$

(3) To construct the subspace $\mathcal{E}_F$, which we will call *physical space* given by the solutions $|\psi_F\rangle$ of the whole set of constraints

$$\mathcal{D}_i |\psi_F\rangle = 0 \quad (7)$$

$$\mathcal{H} |\psi_F\rangle = 0 \quad (8)$$

At this point we will consider a function $T(q_a)$ of the dynamical variables and we will discuss which conditions should be satisfied by this function in order to be considered a time variable for the system.

(I) The first condition that we will require is

$$[T, \mathcal{D}_i] = 0 \text{ and } [T, \mathcal{H}] \neq 0 \quad (9)$$

The vanishing of the commutator between T and $\mathcal{D}_i$ imply that T is a well defined operator in $\mathcal{E}_K$ ($T | \psi_K \rangle \in \mathcal{E}_K$), while the nonvanishing of the commutator between the hamiltonian constraint and T , together with conditions III and IV insure that the hamiltonian restrict the evolution in t of the wavefunctions. This condition is not independent of the other conditions. In fact, if the hamiltonian commutes with T condition IV obviously fails.

(II) We will require that the eigenvectors of T span the kinematical space $\mathcal{E}_K$. In other words, there exist a basis $|x, t\rangle$ of $\mathcal{E}_K$ such that

$$T |x, t\rangle = t |x, t\rangle \quad (10)$$

where the x correspond to additional labels necessary to characterize the vector unambiguously.

We shall consider the vector space $\mathcal{E}_{Kt}$ defined as the subspace of $\mathcal{E}_K$ spanned by $|x, t\rangle$ for a given t . One can define an analogous vector space $\mathcal{E}_{Ft}$ with the projection of the vectors of the physical space

$$| \psi_F \rangle = \sum_{xt} \psi_{Ft}(x, t) |x, t\rangle \quad (11)$$

for a given t

$$| \psi_F, t \rangle = \sum_x \psi_{Ft}(x, t) |x, t\rangle \quad (12)$$

$\mathcal{E}_{Ft}$ may be considered as the projection of $\mathcal{E}_F$ on $\mathcal{E}_{Kt}$. We will introduce evolving systems by considering the logical possibility that the components of a given $\psi_F(x, t)$ of vectors in the physical space $| \psi_F \rangle$ might vanish identically for $t < t_0$. Thus, one may classify these vectors by the value t_0 . We shall say that $| \psi_F^{t_0} \rangle$ is from level t_0 if and only if

$$\psi_F^{t_0}(x, t) \equiv 0 \quad \forall t < t_0$$

We will consider now the operators $O_i(q_a)$ in $\mathcal{E}_K$ that commute with all the constraints (including the hamiltonian constraint) Following Kuchar we shall call these operators perennials.

(III) The next condition that we are going to require is that there exist a subset of $\mathcal{E}_{Kt}$, denoted $\mathcal{E}^*_{Kt}$ with a positive definite inner product

$$\langle \psi_K | \phi_K \rangle_t = \sum_x \psi_K^*(x, t) \phi_K(x, t) \mu(x, t) \quad (13)$$

and that there is a set of perennials such that:

(a) they are selfadjoint with this inner product, provided their classical counterpart be real, and commute with T , $[T, O_i] = 0$.

It follows that this subset of operators doesn't mix vectors lying in different time sections, what imply that they are block diagonal in $\mathcal{E}_K$, in other words

$$O_i \mathcal{E}_{Kt} \subset \mathcal{E}_{Kt} \quad (14)$$

and

$$O_i \mathcal{E}_{Ft} \subset \mathcal{E}_{Ft} \quad (15)$$

(b) their eigenvectors in $\mathcal{E}_{Ft}$ labeled by $|\psi_{F\alpha_i}^{t_\alpha}, t\rangle$ satisfy

$$O_i |\psi_{F\alpha_i}^{t_\alpha}, t\rangle = \alpha_i |\psi_{F\alpha_i}^{t_\alpha}, t\rangle \quad (16)$$

for any t and α_i independent on t .

The eigenvectors corresponding to different eigenvalues are orthogonal.

(c) their restriction to $\mathcal{E}_{Ft}$ is a complete set of commuting observables (CSCO).

We impose that the inner product in $\mathcal{E}_{Ft}^*$ (induced by the inner product in $\mathcal{E}_{Kt}^*$) is such that the eigenvectors of the perennial operators satisfy the orthonormality condition

$$\langle \psi_{F\alpha}^{t_\alpha} | \psi_{F\beta}^{t_\beta} \rangle_t = \theta(t - t_\alpha) \theta(t - t_\beta) \delta_{\alpha\beta} \quad (17)$$

where $\theta(t - t_\alpha)$ is the Heaviside function.

Notice that a basis in $\mathcal{E}_{Ft}^*$ includes all the vectors $|\psi_{F\alpha}^{t_\alpha}\rangle$ of level less or equal to t .

We are going to be interested, in considering as physical observables, not only constants of the motion but more general operators. We shall call an operator A an observable if and only if

$$[A, \mathcal{D}_i] = [A, T] = 0 \quad (18)$$

and therefore A is block diagonal in $\mathcal{E}_K$, A is self adjoint with respect to the inner product and the eigenvectors of A expand $\mathcal{E}_{Kt}$. Notice that while we have required that any perennial commuting with T is selfadjoint, here one may have classical real dynamical variables that are not associated with a selfadjoint operator and consequently they are not observables.

(IV) The last property that we shall require to our time variable is that

$$\mathcal{E}_{Kt}^* \equiv \mathcal{E}_{Ft}^* \quad (19)$$

This condition essentially implies that the hamiltonian constraint determines the evolution of the states but it does not restrict their functional dependence at a given t .

In general $A | \psi_F \rangle$ will not be an element of $\mathcal{E}_F$. However the condition **IV** allows to determine a vector of the physical space that coincides in $\mathcal{E}_t$ with any eigenvector of A . Let

$$A | a_\mu, t \rangle = a_\mu(t) | a_\mu, t \rangle, \quad (20)$$

then the restriction of the physical state

$$| \psi_F(a_\mu, t_0) \rangle = \sum_{t_\alpha \leq t_0}^\alpha \langle \psi_{F\alpha}^{t_\alpha} | a_\mu, t_0 \rangle_{t_0} | \psi_{F\alpha}^{t_\alpha} \rangle \quad (21)$$

to $\mathcal{E}_{Kt_0}$ is equal to $| a_\mu, t_0 \rangle$, and then

$$\langle x, t | a_\mu, t \rangle = \sum_{t_\alpha \leq t}^\alpha \langle x, t | \psi_{F\alpha}^{t_\alpha} \rangle_t \langle \psi_{F\alpha}^{t_\alpha} | a_\mu, t \rangle_t \quad (22)$$

Notice that from condition **III** it follows that $| \psi_F(a_\mu, t_0) \rangle$ exists and is unique, therefore we know how to compute the transition amplitudes between the eigenvectors of two observables A and B at different times

$$\langle b_\nu, t' || a_\mu, t \rangle = \sum_{t_\alpha \leq t}^\alpha \langle b_\nu, t' | \psi_{F\alpha}^{t_\alpha} \rangle_{t'} \langle \psi_{F\alpha}^{t_\alpha} | a_\mu, t \rangle_t \quad (23)$$

where we have introduced the notation $\langle || \rangle$ to distinguish the transition amplitudes from ordinary inner products at t . In other form we have

$$\langle b_\nu, t' || a_\mu, t \rangle = \langle \psi_F(b_\nu, t') | \psi_F(a_\mu, t) \rangle_{t'} \quad (24)$$

These amplitudes contain all the basic information required to determine the evolution of the system. Notice that within this context neither all the perennials are observables nor all the observables are perennials.

The state $| \psi_F(a_\mu, t_0) \rangle$ has been prepared by the measurement of the observable A at time t_0 . Notice that two states prepared at times t_0 and t_1 are such that $\langle \psi_F(a_\mu, t_0) | \phi_F(b_\nu, t_1) \rangle$ is time independent for all $t \geq t_0$ and $t \geq t_1$, *this is the "unitarity" condition for an evolving system.*

In the next section, we shall see that these conditions define a natural extension of the deparametrizable systems.

3 Deparametrizable Models

In this section we want to determine the set of necessary and sufficient conditions that a totally constrained dynamical system should obey in order to be

deparametrizable. We are going to prove that the set of conditions given in the previous section contain as a particular case the deparametrizable systems. Consequently our formalism may be considered as an extension of the usual quantization procedure for deparametrizable systems. In a deparametrizable model there is a (non-canonical) transformation leading from the original set of dynamical variables q_a , to a new set of variables T , p_T and k_a $a = 1, \dots, f - 2$ satisfying the algebra

$$[k_a, k_b]_{\pm} = \alpha_{ab}^c k_c + \beta_{ab} \quad (25)$$

$$[T, p_T]_{-} = i \quad (26)$$

$$[k_a, T]_{-} = [k_a, p_T]_{-} = 0 \quad (27)$$

such that the hamiltonian constraint takes the form

$$\mathcal{H} = p_T + H(k_a, T) \quad (28)$$

The other kinematical constraints have the form

$$\phi_j(k_a, T) = 0 \quad (29)$$

Here we shall restrict our analysis to the case where the only constraint is the hamiltonian constraint. The generalization of the following considerations to the case in which there is a set time independent kinematical constraints $\phi_j(k_a) = 0$ is straightforward.

From the algebra it follows that we can write the representation space as a tensor product of two spaces $\mathcal{E}_R \equiv \mathcal{E}_T \otimes \mathcal{E}_Q$ in which one realize on one hand T and p_T and in the other hand the k_a 's. We will chose the basis

$$|x, t\rangle = |x\rangle |t\rangle \quad (30)$$

where x correspond to the set of labels required to specify the vector in $\mathcal{E}_Q$. An arbitrary vector in $\mathcal{E}_R$ will be

$$|\psi\rangle = \sum_{xt} \psi(x, t) |x\rangle |t\rangle \quad (31)$$

A positive definite inner product is introduced in $\mathcal{E}_Q$

$$\langle \psi | \phi \rangle = \sum_x \psi^*(x, t) \phi(x, t) \quad (32)$$

such that H is a hermitian operator in $\mathcal{E}_Q$.

The action of the operators will be

$$T\psi(x, t) = t\psi(x, t) \quad (33)$$

$$p_T\psi(x, t) = -i\frac{\partial}{\partial t}\psi(x, t) \quad (34)$$

$$k_a\psi(x, t) = \sum_{x'} (k_a)_{xx'} \psi(x', t) \quad (35)$$

With this definitions the hamiltonian constraint

$$\mathcal{H} | \psi_F \rangle = [p_T + H(k_a, T)] \psi_F \rangle = 0 \quad (36)$$

becomes a Schroedinger equation

$$-i \frac{\partial}{\partial t} \psi_F(x, t) + \sum_{x'} (H(t))_{xx'} \psi(x', t) = 0 \quad (37)$$

Such kind of systems will have $f - 2$ constants of the motion (or perennials) $O_i(k_a, t)$ associated to the initial conditions of the system. They satisfy

$$\frac{i\partial O}{\partial t} - [H, O] = 0 \quad (38)$$

Now, a complete set of compatible perennials define a non degenerate basis in E_Q

$$O_i(t_0) | \alpha_i \rangle = \alpha_i | \alpha_i \rangle \quad (39)$$

and

$$| \psi_F^{\alpha_i}, t \rangle = U(t, t_0) | \alpha_i \rangle | t_0 \rangle \quad (40)$$

where U is the evolution operator in E_Q

$$\frac{i\partial U}{\partial t} = HU \quad (41)$$

The vectors $| \psi_F^{\alpha_i}, t \rangle$ are eigenvectors of $O_i(t)$ with eigenvalues α_i and span the physical space. Thus, there is an isomorphism for any t_0 between the restriction $\mathcal{E}_F^* t_0$ and $\mathcal{E}_Q^*$ which is also isomorphic to $\mathcal{E}_K^* t_0$, spanned by $| x \rangle | t_0 \rangle$. To conclude in the case of a deparametrizable system, conditions **(I)**, **(II)** and **(IV)** hold while condition **(III)** is satisfied with the usual time independent inner product and the eigenvectors of the complete set O_i obey the orthonormality conditions

$$\langle \psi_{F\alpha_i} | \psi_{F\alpha_j} \rangle_t = \langle \alpha_i | \alpha_j \rangle = \delta_{ij} \quad (42)$$

instead of (17). Thus, all the states are of the same level $t = t_I$, taken as the origin of time.

Let us now study the converse. Let $T(q)$ be a time variable satisfying conditions **I** to **IV** in the particular case that all the states are of level $t = t_I$ and the inner product have the form (32). Let O_i be a complete set of observables with eigenvectors $| \psi_{F\alpha} \rangle$ that form a complete basis on $\mathcal{E}_{Ft}^* = \mathcal{E}_{Kt}^*$ and therefore satisfy the closure relation

$$\sum_{\alpha} | \psi_{F\alpha}, t \rangle \langle \psi_{F\alpha}, t | = I_t \quad (43)$$

where I_t is the identity operator in $\mathcal{E}_{Kt}^*$. Given an arbitrary state $|\phi\rangle \in \mathcal{E}_{Kt_0}^*$, there is a vector of the physical space $|\phi_F\rangle$

$$|\phi_F\rangle = \sum_{\alpha} |\psi_{F\alpha}\rangle \langle \psi_{F\alpha} | \phi \rangle_{t_0} \quad (44)$$

such that $|\phi_F, t_0\rangle = |\phi\rangle$. That implies

$$\begin{aligned} \phi_F(x, t) &= \sum_{\alpha} \sum_{x'} \psi_{F\alpha}(x, t) \psi_{F\alpha}^*(x', t_0) \phi(x', t_0) \\ &= \sum_{x'} D(x, t; x', t_0) \phi(x', t_0) \end{aligned} \quad (45)$$

Making use of the orthonormality conditions (17) for vectors of level t_I one can show that this relation is invertible. Thus one can write

$$\begin{aligned} i \frac{\partial \phi}{\partial t}(x, t) &= \sum_{x', x''} i \frac{\partial D}{\partial t}(x, t; x'', t_0) D(x'', t_0; x', t) \phi(x', t) \\ &= \sum_{x'} H_{xx'} \phi(x', t) \end{aligned} \quad (46)$$

It is immediate to show from (45) making use of (43) and (17) that the inner product is conserved $\langle \psi | \phi \rangle_t = \langle \psi | \phi \rangle_{t_0}$, and therefore the hamiltonian H is hermitic. Thus we recover the Schroedinger equation for a deparametrizable system. One can easily prove by making use of (46) and the definition of the perennial operators that they also satisfy the evolution equation (38). Consequently the set of conditions given in the previous section are a generalization of the usual quantization procedure for deparametrizable systems. In the next section we will show several examples of evolving systems.

4 Applications

We shall now apply the set of conditions that we have just established, to several systems that require an intrinsic definition of time. The first and simpler example is the parameterized free particle in 1+1 dimensions. As a second example we shall consider a discrete constrained system with an evolving Hilbert space. As a third example we shall consider a continuous system that behaves as the continuum limit of the previous model. We shall introduce an unitary isomorphism that will allow to describe this system in a fixed Hilbert space. We shall prove that the system still have perennials with new eigenvalues and eigenvectors at each level t satisfying the generalized orthonormality condition [17].

4.1 The parameterized particle

The parametrized particle obviously is a deparametrizable system and therefore there is a time variable satisfying conditions **I** to **IV**. However it is interesting to discuss how these conditions determine the time variable. The dynamics of the parameterized particle is contained in the hamiltonian constraint

$$\mathcal{H} = P_1 + \frac{P_2^2}{2m} = 0 \quad (47)$$

which is quadratic in the momentum P_2 . Let us make the natural choice $t = x_1$. At the quantum level the kinematical space $\mathcal{E}_K$ is given in the basis $|x_1, x_2\rangle$ by functions $\psi(x_1, x_2)$ while the physical space is restricted by the hamiltonian constraint

$$\mathcal{H}\psi_F(x_1, x_2) = -i\frac{\partial\psi_F}{\partial x_1} - \frac{1}{2m}\frac{\partial^2\psi_F}{\partial x_2^2} = 0 \quad (48)$$

The physical states may be written in term of the Fourier Transform as

$$\psi_F(x_1, x_2) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dp_2 e^{i(p_2 x_2 - \omega(p_2) x_1)} f(p_2) \quad (49)$$

where

$$\omega(p_2) = \frac{1}{2m} p_2^2 \quad (50)$$

We introduce the inner product of two physical states ψ_1 and ψ_2 in $\mathcal{E}_{Ft}$

$$\langle \psi_1 | \psi_2 \rangle_t = \int_{t=x_1} dx_2 \psi_1^*(x_1, x_2) \psi_2(x_1, x_2). \quad (51)$$

In this particular case, the vector spaces $\mathcal{E}_{Ft}$ for different t are isomorphic. The perennial operators that commute with the time operator X_1 are

$$P_2 \text{ and } X_2 - \frac{P_2}{m} X_1 \quad (52)$$

and a complete set of commuting perennials is formed by P_2 which obviously is self adjoint with the inner product (31) and satisfy condition **II**. Their eigenvectors

$$\psi_{Fp_2}(x_1, x_2) = e^{i(p_2 x_2 - \omega(p_2) x_1)} \quad (53)$$

form an "improper" orthonormal basis of the physical state space, according with condition **III**. Finally it is immediate to check that any square integrable function $\psi(x_1^0, x_2)$ belonging to $\mathcal{E}_{Kx_1^0}^*$, the functional space of fixed $x_1 = x_1^0$, may be expanded in terms of the $\psi_{Fp_2}(x_1^0, x_2)$ that form a complete basis of the kinematical space at x_1^0 . Thus the complete set of conditions is satisfied and the usual formalism of quantum mechanics is recovered with x_1 as the intrinsic time of the system. Before concluding this example, let us briefly mention what happens if we take as a "time variable" the coordinate x_2 . Condition **I** and **II** still holds but one can easily check that **III** and **IV** cannot be simultaneously satisfied.

4.2 A relational systems with a finite dimensional evolving Hilbert space

In this example we want to show a system where the set of conditions for an intrinsic time holds provided its Hilbert space evolves in time. This kind of model shows how evolving Hilbert spaces arise within this approach .

We consider a system formed by the tensor product of two subsystems with angular momentum j , integer,

$$\mathcal{E}_K = \{|j, m_1\rangle \otimes |j, m_2\rangle \equiv |m_1, m_2\rangle, \quad m_1 \geq m_2\}. \quad (54)$$

The system is constrained by a hamiltonian constraint

$$\mathcal{H} = J_0 - J_1 \quad (55)$$

where

$$J_0 |m_1, m_2\rangle = 2(j + m_2 + 1) |m_1, m_2 + 1\rangle \quad (56)$$

$$J_1 |m_1, m_2\rangle = 2(j + m_2) |m_1, m_2\rangle \quad (57)$$

We introduce a discrete time operator in $\mathcal{E}_K$ such that

$$T |m_1, m_2\rangle = (2j - m_1 + m_2) |m_1, m_2\rangle = t |m_1, m_2\rangle \quad (58)$$

One can easily see that $0 \leq t \leq j$. Any state of the basis $|m_1, m_2\rangle$ in $\mathcal{E}_K$ may be labeled by the value of t and the total third component of the angular momentum, M .

We have

$$\begin{array}{llll} t=0 & |j, -j\rangle & \Rightarrow & |t=0, M=0\rangle \quad \dim \mathcal{E}_{K0} = 1 \\ t=1 & \begin{array}{l} |j-1, -j\rangle \\ |j, -j+1\rangle \end{array} & \Rightarrow & |t=1, M=\pm 1\rangle \quad \dim \mathcal{E}_{K1} = 2 \\ t=2 & \begin{array}{l} |j-2, -j\rangle \\ |j-1, -j+1\rangle \\ |j, -j+2\rangle \end{array} & \Rightarrow & \begin{array}{l} |t=2, M=\pm 2\rangle \\ |t=2, M=0\rangle \end{array} \quad \dim \mathcal{E}_{K2} = 3 \end{array} \quad (59)$$

with

$$\dim \mathcal{E}_{Kt} = t + 1$$

and $M+t \geq 0$ The physical state space is defined by functions $\psi_F(t, M)\theta(M+t)$ such that

$$(M+t)[\psi_F(t, M) - \psi_F(t-1, M-1)] = 0 \quad (60)$$

The operator J_{1z} , explicitly given by

$$J_{1z}\psi(t, M) = \frac{1}{2}(2j - t + M)\psi(t, M) \quad (61)$$

is a perennial and commutes with T . The eigenvectors of J_{1z} define a basis in the physical state space

$$\psi_{Fm_1}^{j-m_1}(t, M) = \delta_{M, 2m_1-2j+t} \theta(t-j+m_1) \quad (62)$$

This wave functions vanish for $t < j - m_1$ and therefore they have level $j - m_1$. The inner product

$$\langle \psi | \phi \rangle_t = \sum_{M=-t}^t \psi^*(t, M) \phi(t, M) \quad (63)$$

insures the hermiticity of J_{1z} , and the inner product between the elements of the physical basis satisfy the orthonormality condition

$$\langle \psi_{Fm_1}^{j-m_1} | \psi_{Fm'_1}^{j-m'_1} \rangle_t = \delta_{m_1 m'_1} \theta(t-j+m_1) \quad (64)$$

Thus conditions (I) to (III) are satisfied, the last condition also holds, in fact any function of M at a given t may be obtained by superposition of elements of the physical basis $\psi_{Fm_1}^{j-m_1}(t, M)$ at this t .

Now, it is very easy to compute a transition amplitude between two eigenstates of any observable. For instance if we consider the operator J_{2z} given by

$$J_{2z} \psi(t, M) = \frac{1}{2} (M - 2j + t) \psi(t, M) , \quad (65)$$

it is selfadjoint and commutes with T . Now at time $t = 1$ $| t = 1, M = 1 \rangle$ is an eigenvector

$$J_{2z} | 1, 1 \rangle = (1 - j) | 1, 1 \rangle \quad (66)$$

If we label its eigenvectors at time t by $| m_2, t \rangle$, the transition amplitude between this states and $| m_2 = -j + 1, t \rangle$ is given by

$$\langle m_2 = -j + 1, t = 1 || m_2, t \rangle = \delta_{m_2, -j+t} \quad (67)$$

4.3 An evolving system with an infinite dimensional Hilbert space

Evolving systems in continuum space with a continuous intrinsic time may be simply introduced. The following example is the continuous extension of the model that we have just considered in subsection (3.3)

$$\mathcal{E}_K = \{ | a, b \rangle , \quad a, b \in R \quad a \geq b , \quad -1 \leq a, b \leq 1 \} \quad (68)$$

with hamiltonian constraint

$$\mathcal{H} = 4(a-1)(b+1) \frac{\partial}{\partial b} \psi(a, b) = 0 \quad (69)$$

Then if one chooses as a time variable $t = 2 - a + b$, and $x = a + b$ the hamiltonian constraint takes the form

$$\mathcal{H}\psi(x, t) = (x^2 - t^2) \left[\frac{\partial}{\partial t} \psi(x, t) + \frac{\partial}{\partial x} \psi(x, t) \right] = 0 \quad (70)$$

A complete set of perennials satisfying condition **(III)** is given by

$$A\psi(x, t) = a\psi(x, t) \quad (71)$$

with eigenvectors belonging to the physical space given by

$$\psi_{Fa}^{1-a}(x, t) = \delta(x - t + 2 - 2a)\theta(t - 1 + a) \quad (72)$$

The inner product is given by

$$\langle \psi | \phi \rangle_t = \int_{-t}^{+t} dx \psi^*(x, t) \phi(x, t) \quad (73)$$

and the eigenfunctions verify the orthogonality condition

$$\langle \psi_{Fa}^{1-a} | \phi_{Fa'}^{1-a'} \rangle_t = \frac{1}{2} \delta(a - a') \theta(t - 1 + a) \theta(t - 1 + a') \quad (74)$$

Thus, contitions **(I)** to **(IV)** obviously hold in this system that describes waves propagating in a region bounded by the future light cone. By now, we have a description in terms of an inner product with a time dependent measure. In the continuous case it is always possible to introduce an unitary isomorphism between the Hilbert spaces at two different times. Let us consider this transformation in the present case.

Let

$$\psi'(x, t) = \sqrt{t} \psi(xt, t) \quad (75)$$

then

$$\begin{aligned} \langle \psi'(t) | \phi'(t) \rangle &= \int_{-1}^1 dx \psi'^*(x, t) \phi'(x, t) = \\ &= \int_{-t}^t du \psi^*(u, t) \phi(u, t) = \langle \psi | \phi \rangle_t \end{aligned} \quad (76)$$

where $u = xt$. Thus the unitary transformation is given by

$$U_t^\dagger(u, x) = \sqrt{t} \delta(u - xt) = U_t(x, u) \quad (77)$$

and the eigenvalue equation for the perennial operator takes the form

$$A' \psi'_a(x, t) = \left[\frac{xt - t}{2} + 1 \right] \psi'_a(x, t) = a \psi'_a(x, t) \quad (78)$$

while the the hamiltonian constraint now becomes

$$\mathcal{H}'\psi'(x, t) = (x^2t^2 - t^2)\left[\frac{(1-x)}{t}\frac{\partial}{\partial x} + \frac{\partial}{\partial t} - 1/2t\right]\psi'(x, t) = 0 \quad (79)$$

A complete set of eigenvectors of the perennial operator belonging to the physical space is

$$\psi_{Fa}^{1-a}(x, t) = \sqrt{t}\delta[(x-1)t + 2 - 2a] \quad (80)$$

Notice that these solutions still have level $1-a$ and verify the orthogonality condition

$$\langle \psi_{Fa}^{1-a}(t) | \phi_{Fa'}^{1-a'}(t) \rangle = \frac{1}{2}\delta(a-a')\theta(t-1+a)\theta(t-1+a') \quad (81)$$

Thus, we see that the the fundamental properties of the evolving relational systems the appearance of new eigenvalues and eigenstates at each level and the conservation of the inner product among states of level t_0 for any $t \geq t_0$, are still present in this description in terms of a fixed Hilbert space. In general, evolving Hilbert spaces seem to be naturally related with systems with boundaries. For instance the system we have just analized may be simply generalized to a Klein Gordon system $\mathcal{H} = P_t^2 - P_x^2$ in a bounded region $R = (x, t) : t^2 - x^2 \geq 0$. This system may be treated as a deparametrizable system by introducing a time variable $\tau = \sqrt{t^2 - x^2}$, leading to a usual Klein Gordon equation with a nonpositive definite inner product. However, an equivalent hamiltonian in the bounded region $\mathcal{H}' = (x+t)(P_t^2 - P_x^2)$ may be quantized with a positive definite inner product in an evolving Hilbert space.

5 Conclusions and Final Remarks

We have introduced a notion of intrinsic time in relational systems that allow to recover the fundamental features of time in quantum mechanics. In the case of any standard quantum mechanical systems in parameterized form our method reproduce the usual formalism of quantum mechanics.

However the method allows to include relational dynamical systems and leads naturally to quantum mechanical systems with an evolving Hilbert space. In that sense we are implementing the intuition that one can define fixed time Hilbert spaces that contain subsets of all possible states of the system. These systems are not invariant under time translations or time reversal and have a defined arrow of time. The initial state of the system, as well as the evolution of the Hilbert space, are determined by the hamiltonian constraint and therefore dictated by the dynamics. The number of accessible states increases in time.

Let us conclude with some final comments about the quantum gravity case. Even though very little is known about the physical state space of quantum gravity, a pure gravity system could behave as an evolving system of this type. In fact, it is natural to take as the configuration space of quantum general relativity the loop space [12], because in this representation the domain of the wave functions seems to be simply related with the microscopic structure of space time. In the loop representation, the kinematical space $\mathcal{E}_K$ is given by the knot dependent functions [12] $\psi[K]$ that satisfy the diffeomorphism constraint. As a candidate for the intrinsic time t , we would like to take a variable such that the simplest configuration correspond to its initial value. A good candidate seem to be the minimum number of crossings of a knot, this knot invariant quantity may be used to characterize the complexity of each knot. The kinematical space of quantum gravity will be characterized by wave functions $\psi(t, \kappa)$ where κ are the remaining knot invariants necessary to describe a knot with minimum number of crossings equal to t . If we do not include knots with more than triple selfintersections, the number of independent knot invariants with a fixed t is finite and increases with t . Of course, if we want to take as a time variable some knot invariant such that the number of independent knots and the dimension of the kinematical space increases with t , there is not a unique choice. For instance, one could define as time the degree of an universal polynomial associated with the link. However, up to now, it is not known how to classify any knot in terms of knot polynomials in such a way that inequivalent knots always correspond to different polynomials.

In general relativity no perennial is known, but a candidate to observable, in the sense used in this paper, is given by the volume of the Universe. The eigenstates of the volume operator are knot states having a definite number of crossings and intersections and its eigenvalues are essentially proportional to the Planck volume times the number of intersections. This operator does commute with the diffeomorphism constraint and with our "time" and does not commute with the hamiltonian constraint. These are the conditions required to our observables. The naive picture of the Big Bang that we get is a unique zero volume state that evolves with certain probabilities to different states of finite volume. Within this description the recollapse of the Universe will be associated with a decreasing volume while the complexity of the knot space is still growing. Unfortunately, it does not seem to be easy to check a proposal of this type on a simple cosmological model. In fact, in that case the knot structure related with the diffeomorphism invariance is not present.

Acknowledgements

We wish to thank to Daniel Armand-Ugon, Alcides Garat, Don Marolf, Jose Mourao Jorge Pullin and Lee Smolin for fruitful discussions. One of us R.G. wish to thank the grant NSF-INT-9406269 for partial support.
